## Page 1: Account access

Account access incidents should be handled using the approved identity verification process.

Never request a password, authentication token, or session cookie from the user.

Record the service name, incident timestamp, and sanitized error description.

If a second factor is unavailable, use the documented account recovery workflow.

Keep the ticket limited to the information needed to diagnose the problem.

## Page 2: Network incidents

For a network issue, record which connection type is affected and the approximate start time.

Ask whether the problem affects one device, a room, a building, or remote users.

Do not store private keys or raw credentials in diagnostic logs.

A broad outage should be escalated to the network owner after a status check.

Include a sanitized error message when one is available.

## Page 3: Software requests

Software requests should include the application name, business purpose, and required date.

Check licensing and device compatibility before installation.

If approval is required, link the request to its approval record.

Do not use a software request ticket to store unrelated personal information.

Record the installer version and outcome in the closure note.

## Page 4: Benchmark procedure

Use identical source documents and chunk-size settings for both chunking strategies.

Inspect code blocks, tables, lists, heading paths, and repeated content.

Record exact results and discuss cases where the structure-aware method still fails.

Chunk counts and average lengths alone do not prove improved answer accuracy.

Keep this synthetic test report separate from real institutional records.
